International Journal of Engineering & Technology, 7 (3) (2018) xxx-xxx International Journal of Engineering & Technology Website: www.sciencepubco.com/index.php/IJET doi: Research paper SSVEP-Based Brain-Computer Interface for Computer Control Application Using SVM Classifier Raymond Sutjiadi1*, Timothy John Pattiasina2, Resmana Lim3 1Informatics Department, Faculty of Information Technology, Institut Informatika Indonesia, Surabaya, Indonesia 2Information System Department, Faculty of Information Technology, Petra Christian University, Surabaya, Indonesia *Corresponding Author E-mail: raymond@ikado.ac.id Abstract In this research, a Brain Computer Interface (BCI) based on Steady State Visually Evoked Potential (SSVEP) for computer control appli- cation using Support Vector Machine (SVM) is presented.

For many years, people have speculated that electroencephalographic activity or other electrophysiological measures of brain function might provide a new non-muscular channel

2

2

that can be used

for sending messages or commands to the external world.

 BCI is a fast-growing emergent technology in which researchers aim to
 4

 build a direct channel between the human brain and the computer. BCI
 systems provide a

3

new communication channel for disabled people. Among the many different types of the BCI systems, the

SSVEP based has attracted more attention due to its ease of use and signal processing. SSVEP are usually recorded from the occipital lobe of the brain when the subject is looking at a twinkling light source.

SVM used in classifying SSVEP based electroencephalogram data with proper features. Based on the experiment utilizing 14-channel Electroencephalography (EEG) device, 80 percent of accuracy can be reached using SSVEP-based BCI with Linear SVM Kernel to move mouse cursor into four directions (up, down, left, and right).

Keywords: Brain Computer Interface, Brain Waves, Electroencephalography, **Steady State** Visually **Evoked Potential**,

Support Vector Machine 1. Introduction Currently many different disorders can disrupt the neuromuscular channels through which the brain communicates with and controls its external environment. Amyotrophic lateral sclerosis (ALS), brainstem stroke, brain or spinal cord injury, cerebral palsy, mus- cular dystrophies, multiple sclerosis, and numerous other diseases impair the neural pathways that control muscles or impair the mus- cles themselves. In the absence of methods for repairing the damage done by these disorders,

there are 3 options for restoring function [1]. The first is to increase the capabilities of remaining pathways,

The second option is to restore function by detouring around breaks in the neural pathways that control muscles.

The third option

is to provide the brain with a new, non-muscular communication and control channel, by using a direct Brain Computer Interface (BCI) for conveying messages and commands to the external world. A variety of methods for monitoring brain activity might serve as a BCI. At present, only Electroencephalography (EEG) and related methods,

which have relatively short time constants, can function in most environments, and require relatively simple and inexpen- sive equipment, offer the possibility of a new non-muscular com- munication and control channel, a practical BCI.

EEG is a non- invasive way of acquiring brain waves from the surface of human scalp, which is widely accepted due to its simple and safe approach [2]. Nowadays a lot of research about BCI has been published. BCI technology represents a highly growing field of research with ap-plication systems. Its contributions in medical fields range from prevention to neuronal rehabilitation for serious injuries. Mind reading and remote communication have their unique fingerprint in numerous fields such as educational, self-regulation, production, marketing, security as well as games and entertainment. It creates a mutual understanding between users and the surrounding systems. The research community has initially developed BCIs with biomed- ical applications in mind, leading to the generation of assistive de- vices. They have facilitated restoring the movement ability for physically challenged or locked-in users and replacing lost motor functionality [3]. More recent studies have targeted normal individ- uals by exploring the use of BCIs as a novel input device and inves- tigating the generation of hands-free applications [4]. On the other hand, some of BCI advantages for able-bodied users have been enlightened in. BCI could be helpful especially for ap-plications where it is instantaneously difficult to move and the re-sponse time is crucial. Besides BCI can also be used to increase the accuracy of the HCI systems, resulting in BCI contribution in vari- ous fields such as educational, gaming industry, transportation, and entertainment. Despite its expected success, Brain computer inter- facing needs to overcome technical difficulties as well as challenges posed by user acceptance to deal with such newly discovered tech- nology. 2. Brain-Computer Interface A Brain Computer Interface, sometimes called a Mind-Machine In- terface (MMI), Direct Neural Interface (DNI), or Brain-Machine Interface (BMI), is a direct communication pathway between an en-hanced or wired brain and an external device.

BCI system is a com- munication channel that could assist and increase the performance of both disabled and normal people. In a BCI system, the brain

ac- Copyright © 2016 Authors. This is an open access article distributed under the Creative Commons Attribution License, which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited. tivities

are recorded from the scalp and coded to appropriate exter- nal control commands [5]. Some modalities used for brain activity recording in BCI

applications are Electroencephalography (EEG), magneto encephalography, functional magnetic resonance imag- ing and near infrared spectroscopy [6]. However, due to its ease of utility and better temporal resolution the EEG is mostly used in BCI systems. BCI systems

build a communication bridge between hu- man brain and the external world eliminating the need for typical information delivery methods. They manage the sending of mes- sages from human brains and decoding their silent thoughts. BCI systems can help handicapped people to tell and write down their opinions and ideas via variety of methods such as in spelling appli- cations [7], semantic categorization [8], or silent speech communi- cation [9]. In the 1970s, research on BCI's started at the University of Califor- nia, which led to the emergence of the expression brain–computer interface. The focus of BCI research and development continues to be primarily on neuroprosthetics applications that can help to re- store damaged sight, hearing, and movement. In 1990s marked the appearance of the first neuroprosthetic devices for humans. BCI does not read the mind accurately, but detects the smallest of changes in the energy radiated by the brain when you think in a certain way. A BCI recognizes specific energy/ frequency patterns in the brain. The

BCI can lead to many applications especially for disabled persons such as: new ways for gamers to play games using their heads, social interactions; enabling social applications to cap- ture feelings and emotions, helping partially or fully-disabled peo- ple to interact with different computational devices, and helping to understanding more about brain activities and human neural net- works. These applications depend on the basic understanding of how the brain works. The BCI

framework is described in several building blocks that need to interact properly as shown in Fig. 1. Different BCIs rely on different mental activities and corresponding EEG patterns. BCI system components, regardless of its type, recording methods or ap-plications, are: 1) signal acquisition, 2) pre-processing 3) feature extraction/selection, 4) classification, 5) application interface. Fig. 1: BCI Framework There are three dominant approaches to BCI systems [10], catego- rized according to the type of mental activity and corresponding brain activity used for control. Three existing types of BCIs are Steady State Visually Evoked Potential (SSVEP), P300, and Event Related Desynchronization and Synchronization (ERD/S) or Motor Imagery (MI). Since each type of BCI relies on brain waves gener- ated at different location of brain, they require electrodes placed on different areas of brain. 2.1. Steady State Visually Evoked Potential Steady State Visually Evoked Potential (SSVEP) BCIs [11][12] rely on attention to lights that flicker at specific frequencies, which elicit corresponding SSVEP signals over occipital areas. The lights might contain messages or commands like letters, words, or device commands. Hence, the BCI can identify target items by identifying which frequencies are apparent over occipital areas. There are some issues about SSVEP BCIs [13], one is gaze dependence. Another issue is that in some users, the flickering stimulus is annoying and produces fatigue. Using higher frequencies for the flickering stimuli reduces the annoyance, but on the other hand, it is harder to detect the SSVEP. SSVEP BCIs have some advantages such as no signif- icant

training requirement and high information transfer rate 2.2. P300 P300 BCIs [14]-[18] are based on the brain response to an event or stimulus considered as event-related potential (ERP) which can de- tect intention of the subject. After stimulus onset, positive and neg- ative deflections occur in the EEG. The largest positive deflection that occurs around 300 milliseconds after the stimulus onset is called "P300" which is the most used ERP component in BCI sys- tems. P300 BCIs rely on the flash of a rare event among frequent events. When users choose to count specific rare target items, each target flash produces P300 signals that are dominant over parieto- occipital areas. Moreover, several P300-based BCI studies found slight reduction in performance during the sessions, which might be due to a habituation effect. Because the P300 is largest for new, relevant, desired events, repeatedly presenting rare events results in decreased P300 amplitudes and thus reduced performance. using a P300-based BCI requires attention and concentration, the user should not be distracted. This could be difficult if the P300-based BCI is used in normal life. 2.3. Event Related Desynchronization and Synchronization ERD BCIs utilize changes in event related desynchronization and synchronization (ERD/S) that usually occur when people imagine specific movements [19]. They have also been called sensorimotor rhythm (SMR) or mu/beta BCIs. Imagining movement produced changes in 8-12 Hz activity over contralateral sensorimotor areas. This activity is in the mu band, and activity in the beta band some- times changes with imagined movement as well. Nowadays, ERD/ERS is one of the most used brain wave patterns in BCIs. It allows the user to consciously manipulate his or her EEG patterns, and therefore it is suited for BCI applications that require the user to actively carry out control, as opposed to for instance P300, where the brain wave pattern is subconsciously altered. This also makes ERD and ERS suitable for identification purposes, since it can be reproduced at will at any time. To design a practical BCI system needs to address several issues such as ease of use, a reliable system performance, and low-cost hardware and software. In recent years, with the biomedical sci- ences and electronics technology, mobile and online BCI's devel- opment has been proposed. Among them in this research SSVEPs are attracted due to its advantages of requiring less or no training, high Information Transfer Rate (ITR) and ease of use [20]. 3. Steady State Visually Evoked Potential

The Steady State Visually Evoked Potential (SSVEP) has recently become a popular paradigm in Brain Computer Interface (BCI) ap- plications. Typically these applications offer the user a binary se- lection of targets that perform correspondingly discrete actions. Such control systems are appropriate for applications that are inher- ently isolated in nature, such as selecting numbers from a keypad to be dialled or letters from an alphabet to be spelled.

The mechanism behind SSVEPs is not yet well-understood, but recently SSVEP- based BCIs have been increasingly employed in research, as they have been demonstrated to be useful in different applications, espe- cially for applications that require a large number of commands and self-paced performances.

1

However motivation exists for users to employ proportional control methods in intrinsically analogue tasks such as the movement of a mouse pointer SSVEP BCI is normally constructed by presenting the user with multiple stimuli that are distinct in repetition rates.

Stimuli can be presented through use of flashing Light Emitting Diodes (LEDS) or alternatively standard Cathode Ray Tube (CRT) or Liquid Crystal Display (LCD) monitors can be employed to output a variety of stimuli through Computer Generated Imagery (CGI). However, this type of presentation is severely limited in the number of distinct stimuli that do not suffer from temporal aliasing due to the compar- atively low refresh rate (60-120Hz) of typical standard visual dis- play units.

1

When using SSVEP, the monitor is used to show moving animation, for example a left arrow moving from right to left. User gazes this animation focally and as the result, brain will emit certain signal pattern to be classified into certain computer task. Another way, monitor is used to show some flickering objects in certain fre- quencies, usually in low frequency. A SSVEP BCI system contains the following modules: a) Stimula- tor module: is a LED panel or a monitor responsible to produce the visual stimuli at a specific frequency; b) Signal acquisition module: is responsible to acquire the EEG signals during the system opera- tion; c) Signal processing module: is responsible for the analysis of EEG signals and the translation/transformation of them into mean- ingful "codewords"; and d) Device commands module: is appointed with the task to translate the "codewords" into interface commands according to the application setup, as shown in Fig. 2. Fig. 2: SSVEP-BCI System The signal processing module consists of four submodules: a) pre-processing, b) feature extraction, c) feature selection and d) classi- fication. The first three submodules have the goal to make the data suitable for the classification process, which will gives us the ap- propriate "codewords", as shown in Fig. 3. Fig. 3: Signal Processing Module of SSVEP BCI System Many methods have been applied in the pre-processing part of a SSVEP-BCI system. The most common of them is the filtering, and most specifically the band pass filtering. Various filters have been used at this point of analysis procedure depending of the particular needs of each SSVEP-BCI system, such as band pass IIR filter from 22-48Hz and more specifically, the Common Averaging Re-refer- encing (CAR) [22] spatial filtering method is used in to spatially filter the multichannel EEG signals and remove unwanted compo- nents such as eye blinks. Finally, the decision step in SSVEP BCI system is performed by applying a classification procedure. More specifically, in classifiers [23][24][25] such as the Support Vector Machine (SVM), the Linear Discriminant Analysis (LDA) and Ex- treme Learning Machines (ELM) are used. SVM and LDA are the most popular classifiers among SSVEP community and have been used in numerous works. 4. Support Vector Machine Support Vector Machine (SVM) was first heard in 1992, introduced by Boser, Guyon, and Vapnik in COLT-92. SVM are a set of related supervised learning methods used for classification and regression [26]. They belong to a family of generalized linear classifiers. In another terms, SVM [27] is a learning structure that can be used to solve classification and regression prediction tool that uses machine learning theory to maximize predictive accuracy while automati- cally avoiding overfit to the data. Support Vector Machines (SVM) can be defined as systems which use hypothesis space of a linear functions in a high dimensional feature space,

trained with a learn- ing algorithm from optimization theory that implements a learning bias derived from statistical learning theory. In the context of clas- sification it can be understood as a maximal margin classifier whose linear or non-linear structure is defined by a kernel function. The design of a classifier of this kind gives rise to a quadratic con-strained optimization task that can be solved using a number of ef-ficient computational tools. In a classification system, the SVM fol- lows two stages: training and classification. The advantage of SVM is that once a boundary is established, most of the training data is redundant. All it needs is a core set of points which can help identify and set the boundary. These data points are called support vectors because they "support" the boundary. In the training, labeled data are used in order to determine the hyperplane in a high-dimensional feature space that distinguish the classes with maximal margin. In practice, the training can be per-formed in the original data space using different kernel functions as linear, quadratic, polynomial, multilayer perceptron (MLP) or Gaussian radial basis (RBF)[28]. In this research a linear kernel function was selected after prelimi- nary tests with several methods, in view of its stability for multiple trials. An example of SVM classification as shown in Fig. 4. Fig. 4: Sample Hyper Planes Data Classifier [29] As shown in Fig. 4, there are many linear classifiers (hyper planes) that separate the data. However only one of these achieves maxi- mum separation. Next step is we try to give the maximum margin classifier which provides a solution to the above mentioned prob- lem shown by Fig. 4 Fig. 5: Linear Support Vector Machines (LSVM) As shown in Fig. 5, the maximum linear classifier with the maxi- mum range using Linear Support Vector Machine (LSVM) can solved the problem. This example is simple linear SVM classifier. The goals of SVM are separating the data with hyper plane and ex- tend this to non-linear boundaries using kernel trick [30]. Assume the training data of D with a set of n points of calculating by Eq. 1: (1) where the yi is either 1 or -1, indicating the class to which the point xi belongs. Each xi is a Pdimensional real vector. We want to find the maximum-margin hyper plane that divides the points having yi = 1 from those having $y_i = -1$. Any hyper plane can be written as the set of points X satisfying following Eq. 2: -=0 (2) where \cdot denotes the dot product and W denotes the normal vector of hyper plane. The parameter determines the offset of the hy- b ||W|| per plane from the origin along the normal vector W. For maximization distance in point for linearly separable data the margin is set. The set margin hyper plane is described in Eq. 3: $\cdot - = 1$ and $\cdot - = -1$ (3) Geometrically, the distance between these two hyper planes is 2, ||W|| so to maximize the distance between the planes we want to mini- mize ||W||. To prevent the data points to fall into the margin, the following constraint is added: for each i either, $W \cdot X - b \ge 1$ For xi of first class; $W \cdot X - b \le 1$ For xi of second class. The final equation is written as Eq. 4: $(\cdot -) \ge 1$, for all $1 \le \le 1$ (4) The extended extension of maximum-margin classifier which pro-vides a solution to the above mentioned problem is given as Eq. 5: x?w ?b margin ? arg min d (x) ? arg min (5) x?D x?D ?id?1 wi2 5. System Design and Implementation For this research, BCI application is built using OpenViBE, an open source software for brain computer interfaces and real time neuro-sciences. OpenViBE is used to develop signal acquisition server that connects to Emotiv Epoc+ as EEG scientific contextual device via Bluetooth interface to gather raw brain waves from 14 different channels. Besides that, OpenViBE is also used to develop signal acquisition client which receive signal from port 1024 and do signal processing. Then, as an output of this signal processing is stimula- tion signal to be sent to VRPN (Virtual Reality Peripheral Network) server, as the demarcation point between BCI system to the operat- ing system. To receive stimulation signal and translate it into cursor movement, an C++ application is developed as VRPN client. Fig. 6 showed complete architecture of BCI system. EEG Device (Emotiv Epoch+) BCI System Signal Acquisition Server (OpenViBE) Signal Acquisition Client (OpenViBE) VRPN Server (.NET VRPN Library) VRPN Client (C++ Application) Fig. 6: BCI Architecture. In part of signal acquisition client, there are 3 sections of signal pre-processing and processing to result final decision in form of partic- ular cursor movement command: 1. Signal epoching and tagging. In this process, raw signal received from EEG device is cap-tured in short duration (1.5s) with interval 0.1s between epochs, as shown in Fig. 7. Then, each

epoch is tagged starting and end- ing point as the boundary of processed signal for the next stage. 2. SSVEP generator. SSVEP generator creates flickered object on screen as visual medium to stimulate brain waves. There are 4 white-square flickered objects with black background to give contrast view to user as shown in Fig. 8. Because LCD screen used in this research has refresh rate 60Hz, each flickered object must be set to flicker using frequency factor of 60, i.e. 15Hz (up direc- tion), 12Hz (left direction), 10Hz (right direction), and 6Hz (down direction). 3. Common Spatial Pattern (CSP) training. Some brain parts are more reactive to receive stimuli. CSP is used as feature extraction to search the best combination of electrodes. By using CSP filter is expected to get better preci- sion for classifier training by removing unwanted signals. 4. Signal filtering. Before entering SVM classifier, signal is filtered once again to remove any noise using band pass filter. Also applied simple Digital Signal Processing (DSP) and signal average to boost quality of signal to be processed as training model on the next step. 5. Classifier training. This is the main section of the BCI system. In this section, model signals will be used to train SVM classifier. Tuning the SVM parameter is required to get better accuracy. The result of this section is SVM classifier model, which will be used to pre- dict the online testing scenario. 6. Predicting. Final process is doing online testing scenario by using SVM classifier model. The prediction output is received by VRPN server and then translate it into respective stimulation signal. This stimulation signal then sent to VRPN client. Fig. 7: 14-Channel Raw Brain Waves Fig. 8: SSVEP Stimulator After signal processing in acquisition client and VRPN server, then stimulation signal is delivered to VRPN client. In VRPN client, this stimulation signal is converted into command to move mouse cur- sor to respective direction according the SVM prediction. A C++ application is developed to trigger cursor movement accordance with received stimulation signal. Below is the chunk of C++ code to do cursor movement: #include <windows.h> #include <iostream> #include "vrpn\include\vrpn_Button.h" int x, y; int stop = 0; void VRPN_CALLBACK vrpn_button_callback(void* user_data, vrpn_BUTTONCB button) { if (button.button == 1) { SetCursorPos(x-5, y); } if (button.button == 2) { SetCursorPos(x+5, y); } if (button.button == 0) { SetCursorPos(x, y-5); } if (button.button == 3) { SetCursorPos(x, y+5); } if (button.button == 10) { *(bool*)user data = false; } } int main(int argc, char** argv) { bool running = true; POINT p; GetCursorPos(&p); x = p.x; y = p.y; vrpn Button Remote* VRPNButton; VRPNButton = new vrpn Button Remote ("openvibe vrpn button@localhost"); VRPNButton->register change handler(&running, vrpn button callback); while (running) { GetCursorPos(&p); x = p.x; y =p.y; VRPNButton->mainloop(); } return 0; } 6. Result and Discussion In order to test the performance and accuracy of SSVEP-based BCI system using SVM classifier, several tests were implemented. All these experiments were used the same optimized parameters as listed below: Epoch duration : 1.5s Epoch interval : 0.1s CSP Filter Dimension : 14 Support Vector Machine Parameters Epsilon : 0.2 SVM Type : C-SVC Degree : 3 Epsilon Tolerance : 0.001 Cost : 1 Cache Size : 100 Gamma : 0 Nu : 0.5 Shrinking : True Coef 0: 0 Number of Partition: 10 Balance Class: False 6.1. Frequency Tolerance In this section, the accuracy testing was held by tuning the fre- quency tolerance parameter. This frequency tolerance was used to set the point of band pass filter from each respective SSVEP fre- quency. For example: SSVEP frequency for 'Up Direction' = 15Hz and frequency tolerance parameter = 0.5. It meant band pass filter would be set 14.5Hz for High Pass Filter (HPF) and 15.5Hz for Low Pass Filter (LPF). The lower frequency tolerance would eliminate noise better but tighter to detect brain waves range. On the other side, the higher frequency tolerance would increase the noise but wider to detect brain waves range. Table 1 below depicts the result of experiment by tuning frequency tolerance parameter using default SVM kernel type (Linear). Table 1: System Accuracy by Tuning Frequency Tolerance Parameter Prediction No Actual Frequency Tolerance = 0.25 Frequency Tolerance = 0.5 Frequency Tolerance = 0.75 1 Neutral Neutral Neutral Up 2 Down Down Down Down 3 Right Right Up Up 4 Left Left Neutral 5 Up Up Up 0 6 Neutral Neutral Neutral Neutral 7 Down Up Down Down 8 Left Left Left 9 Up Up Up Up 10 Right Up Right 11 Neutral Neutral Neutral Neutral 12 Left Up Left Right 13 Right Up Neutral Up 14 Up Up Right Left 15 Down Down

Kernel Type For second parameter, the experiment would focus on the choosing of SVM kernel type. SVM kernel is algorithm uses a set of mathematical functions that take data as input and transform it into the required form for pattern analysis. It comprise 4 types, i.e.: Linear, Polynomial, Radial Basis Function, and Sigmoid. Choosing the cor-rect algorithm would increase the accuracy of SVM model classifier. This experiment uses the same configuration with the last section and for frequency tolerance uses 0.5 as the best parameter based on the previous experiment section. The result is shown in Table 2. Conclusion BCI is a system that important to help motoric impaired people to access computer as well as the average people. But the implemen- tation of BCI system needs proper signal processing to make it ac- curate because human brain waves are complex and susceptible of noise. Moreover, translating human brain waves pattern to move mouse cursor is guite challenging. The abstract nature of human brain waves pattern should be stimulated using external stimulation. So the specific brain waves pattern can be read and translated by the computer into specific action. This research proposed SSVEP method as the external visual stim- ulation using flickered object on LCD screen to stimulate the oc- currence of similar brain waves frequency pattern. This method is effective and easy to use for motoric disabled people who still has good eyes as the stimuli receptor. The use of correct classifier method is also hold the important part to make accurate BCI system. SVM is chosen because this method is quite efficient and robust to be used as pattern recognition algorithm. This method is also widely used in bioinformatics applica- tion. Based on the experiment utilizing 14channel EEG device, 80 percent of accuracy can be reached using SSVEP-based BCI with Linear SVM to move mouse cursor into four directions (up, down, left, and right). For further refinement, this BCI system should be improved to ac- commodate other mouse operation, like click and double-click function. This will make BCI system more functional and useful for helping disabled people to operate computer.
